Performance of Sorghum Hybrids in Virginia

Maria Balota, Ph.D., Assistant Professor of Crop Physiology

Ames Herbert, Ph.D., Professor of Entomology

Laban Rutto, Ph.D., Virginia State University, Assistant Professor of Agronomy

TECHNICAL SUPPORT:

F. Bryant, Ag Specialist

D. Redd, Ag Specialist

P. Copeland, Office Services Specialist

C. Daughtrey, Ag Technician

B. Kennedy, Ag Technician

T. Balotte, Ag Technician

M. Arrington, Res Specialist

R. Arrington, Res Specialist

S. Malone, Ag Technician

Virginia Polytechnic Institute and State University

Virginia Agricultural Experiment Station

Tidewater Agricultural Research and Extension Center

Suffolk, Virginia 23437

Virginia Tech does not discriminate against employees, students, or applicants on the basis of race, color, sex, disability, age, veteran status, national origin, religion, sexual orientation, or political affiliation. Anyone having questions concerning discrimination or accessibility should contact the Equal Opportunity/Affirmative Action Office

ACKNOWLEDGEMENTS

The authors gratefully acknowledge financial support from the following institutions and organizations:

United Sorghum Checkoff Program

TECHNICAL SUPPORT

The following agricultural specialists and technicians are gratefully acknowledged for their professionalism, and dedication to achieve tasks on time and in a collegial manner: B. Ashburn, F. Bryant, D. Redd, C. Daughtrey, B. Kennedy, P. Copeland, T. Balotte, M. Arrington, R. Arrington and S. Malone.

Pam Copeland

Frank Bryant

Doug Redd (center)

Mike Ellis and Doug Redd

Cooperators are greatly acknowledged for providing expertise and seed

Expertise: Dr. Wade Thomason, Small Grains Specialist at Virginia Tech

Introduction

Based on the data from the U.S. Grain Council (<http://www.grains.org/sorghum>), grain sorghum is the third most important cereal crop grown in the United States and the fifth most important cereal crop grown in the world. The United States is the world's largest producer of grain sorghum followed by India and Nigeria with approximately 9.7 million acres harvested in the 2009/2010 cropping season. In the United States, sorghum production is concentrated in the central and southern plains of five states - Kansas, Texas, Nebraska, Oklahoma and Missouri, representing approximately 89% of total production. In many parts of the world sorghum has traditionally been used for food. In the United States, sorghum is primarily used for animal feed, but also for food and industry derivatives such as wallboard and biodegradable packaging materials. Recently sweet sorghums were considered for bioenergy feedstock production.

Sorghum is one of the most drought tolerant cereal crops currently under cultivation. It offers farmers the ability to reduce costs on irrigation and other on-farm expenses. The International Water Management Institute (IWMI) warns that by the year 2025, 25 percent of the world's population will experience severe water scarcity. However, water productivity in both irrigated and rain-fed acres can be increased through the use of more water-use efficient crops, like sorghum. This and other economic concerns prompted Murphy-Brown, one of the largest animal feed operations in the country, to push for increased sorghum production in Virginia and Carolinas (V-C). For the 2012 Murphy-Brown Sorghum Program, cash price for sorghum will be 95% of the harvest price for corn at selected elevators, one of which is in Waverly, VA.

Before Murphy-Brown became interested in sorghum production in the V-C region, researchers at the Virginia Tech Tidewater Agricultural Research and Extension Center (TAREC) in Suffolk, VA, realized the benefits of a drought tolerant and less input-demanding cereal to replace corn, otherwise a water inefficient crop. With funds provided by the National Sorghum Checkoff Program a hybrid testing program was initiated at TAREC in 2009. In 2012, 45 sorghum hybrids were planted in approximately 240 ft² plots at five locations in Virginia: TAREC; Virginia State University's (VSU) Randolph Farm; and at three commercial fields in Isle of Wight, Sussex and Southampton counties. Plots were replicated three and four times in a randomized complete block design (RCBD).

Results in 2012

Figure 1. Planting sorghum with a NG Plus 3 Monosem two-row precision vacuum planter in plots of two- 40 ft. rows on 36-inch centers.

Data collected on grain yield seed, test weight, seed moisture, corn earworm and other insect damage, heading date (days from planting), and head mold rating are presented here. Heading date was recorded only at TAREC and head mold only at Isle of Wight. Test weight and insect damage was not recorded at the VSU location. Grain yield and seed moisture at harvest were recorded at all locations. Relative yield (Table 12) was calculated as yield percent of individual hybrids from the means of all hybrids tested at individual locations. Only four hybrids yielded over the hybrid means at all locations: GX12353, TRX15401, DKS49-45, and 84G62. Eight more yielded over the hybrid means at four out of five locations: GX12364, GW9320, DKS56-67, NK6638, 83P17, 5613, 06173, and TR463. The hybrids with the lowest yields well below the means at all locations, were 10413 and 3552, and 11 more had significantly lower yields than the hybrid means at the majority of locations: 732B, M75GB39, GX12522, GX123121, 68653, 50113, 0813, TR457, H-39-0W, NK8416, and 5556. It was a positive relationship between the number of days to heading and yield, but the relation was weak. For example, four of the highest yielding hybrids at TAREC, GX12353, 92123, TRX85123, and TRX15401, had 61, 58, 65, and 70 days to heading, respectively. At the same time one of the lowest yielding hybrids at all locations, NK8416, had 68 days to heading.

Cultural Practices in 2012

Table 1. Cultural practices used in sorghum tests in 2012.

Results in 2012

Table 5. Worm¹ and Other² damage (number of plants damaged/plot), the number of corn earworms counted per 10 plants/plot³, and the visual score of head mold⁴ for sorghum hybrids tested at Isle of Wight County, VA, in 2012. The first number of the visual score was 0, no mold, 1, 10% of the heads in a plot with mold, 2-20%, 3-30%, 4-40%, and 5≤ 50% of the heads in a plot were molded. The second number shows the percent mold coverage within a head and was ≥ 2 for less than 25% coverage, 25 for 25% coverage, 50 for 50%, and 75 for ≤ 75% coverage.

Table 13. Chart describing sorghum growth stages and the approximate dates when they occur if planting was on May 15 (courtesy to the University of Illinois, Extension Program for the picture).

Planting date May 15	Emergence (3-10 DFP); May 25	3-leaf stage (10 DAE); good weed control, June 5	5-leaf stage (20 DAE); roots develop fast; June 15	Growing point differentiation & stem elongation (30 DAE); June 25	Stage 4 – all except 3-4 leaves not yet expanded (40 DAE); July 5 Stage 5 – Boot stage (50 DAE); head is fully sized; rapid growth; July 15	Half boom (60 DAE); flowering takes 4 to 9 days; July 25	Soft dough (70 DAE); Aug. 5	Stage 8 – Hard dough (80 DAE); Aug. 15 Stage 9 – physiological maturity (90 DAE); Aug. 25
